(54) Title: AN INDEXED LIBRARY OF CELLS CONTAINING GENOMIC MODIFICATIONS AND METHODS OF MAKING AND UTILIZING THE SAME

(57) Abstract

Methods and vectors (both DNA and retroviral) are provided for the construction of a Library of mutated cells. The Library will preferably contain mutations in essentially all genes present in the genome of the cells. The nature of the Library and the vectors allow for methods of screening for mutations in specific genes, and for gathering nucleotide sequence data from each mutated gene to provide a database of tagged gene sequences. Such a database provides a means to access the individual mutant cell clones contained in the Library. The invention includes the described Library, methods of making the same, and vectors used to construct the Library. Methods are also provided for accessing individual parts of the Library either by sequence or by pooling and screening. The invention also provides for the generation of non–human transgenic animals which are mutant for specific genes as isolated and generated from the cells of the Library.

AN INDEXED LIBRARY OF CELLS CONTAINING GENOMIC MODIFICATIONS AND METHODS OF MAKING AND UTILIZING THE SAME

5 The present application claims priority to U.S. Applications Ser. Nos. 08/726,867, filed October 4, 1996, 08/728,963, filed October 11, 1996, and 08/907,598, filed August 8, 1997, the disclosures of which are herein incorporated by reference.

10 ### 1.0. FIELD OF THE INVENTION

The invention relates to an indexed library of genetically altered cells and methods of organizing the cells into an easily manipulated and characterized Library. The invention also relates to methods of making the library,
15 vectors for making insertion mutations in genes, methods of gathering sequence information from each member clone of the Library, and methods of isolating a particular clone of interest from the Library.

20 ### 2.0. BACKGROUND OF THE INVENTION

The general technologies of targeting mutations into the genome of cells, and the process of generating mouse lines from genetically altered embryonic stem (ES) cells with specific genetic lesions are well known (Bradley, 1991, Cur.
25 Opin. Biotech. 2:823-829). A random method of generating genetic lesions in cells (called gene, or promoter, trapping) has been developed in parallel with the targeted methods of genetic mutation (Allen et al., 1988 Nature 333(6176):852-855; Brenner et al., 1989, Proc. Natl. Acad. Sci. U.S.A.
30 86(14):5517-5521; Chang et al., 1993, Virology 193(2):737-747; Friedrich and Soriano, 1993, Insertional mutagenesis by retroviruses and promoter traps in embryonic stem cells, p. 681-701. In Methods Enzymol., vol. 225., P. M. Wassarman and M. L. DePamphilis (ed.), Academic Press, Inc., San Diego;
35 Friedrich and Soriano, 1991, Genes Dev. 5(9):1513-1523; Gossler et al., 1989, Science 244(4903):463-465; Kerr et al., 1989, Cold Spring Harb. Symp. Quant. Biol. 2:767-776; Reddy et al., 1991, J Virol. 65(3):1507-1515; Reddy et al., 1992,

Proc. Natl. Acad. Sci. U.S.A. *89(15)*:6721-6725; Skarnes *et al.*, 1992, Genes Dev. *6(6)*:903-918; von Melchner and Ruley, 1989, J. Virol. *63(8)*:3227-3233; Yoshida *et al.*, 1995, Transgen. Res. 4:277-287). Gene trapping provides a means to
5 create a collection of random mutations by inserting fragments of DNA into transcribed genes. Insertions into transcribed genes are selected over the background of total insertions since the mutagenic DNA encodes an antibiotic resistance gene or some other selectable marker. The
10 selectable marker lacks its own promoter and enhancer and must be expressed by the endogenous sequences that flank the marker after it has integrated. Using this approach, transcription of the selectable marker is activated and the cell gene is concurrently mutated. This type of strict
15 selection makes it possible to easily isolate thousands of ES cell colonies, each with a unique mutagenic insertion.

Collecting mutants on a large-scale has been a powerful genetic technique commonly used for organisms which are more amenable to such analysis than mammals. These organisms,
20 such as *Drosophila melanogastor*, yeast *Saccharomyces cerevisiae*, and plants such as *Arabadopsis thalia* are small, have short generation times and small genomes (Bellen *et al.*, 1989, Genes Dev. *3(9)*:1288-1300; Bier *et al.*, 1989, Genes Dev. *3(9)*:1273-1287; Hope, 1991, Develop. *113(2)*:399-408.
25 These features allow an investigator to rear many thousands or millions of different mutant strains without requiring unmanageable resources. However, these type of organisms have only limited value in the study of biology relevant to human physiology and health. It is therefore important to
30 have the power of large-scale genetic analysis available for the study of a mammalian species that can aid in the study of human disease. Given that the entire human genome is presently being sequenced, the comprehensive genetic analysis of a related mammalian species will provide a means to
35 determine the function of genes cloned from the human genome. At present, rodents, and particularly mice, provide the best model for genetic manipulation and analysis of mammalian

physiology.

Gene trapping has been used as an analytical tool to
identify genes and regulatory regions in a variety of animal
cell types. One system that has proved particularly useful
5 is based on the use of ROSA (reverse orientation splice
acceptor) retroviral vectors (Friedrich and Soriano, 1991 and
1993).

The ROSA system can generate mutations that result in a
detectable homozygous phenotype with a high frequency. About
10 50% of all the insertions caused embryonic lethality. The
specifically mutated genes may easily be cloned since the
gene trapping event produces a fusion transcript. This
fusion transcript has trapped exon sequences appended to the
sequences of the selectable marker allowing the latter to be
15 used as a tag in polymerase chain reaction (PCR)-based
protocols, or by simple cDNA cloning. Examples of genes
isolated by these methods include a transcription factor
related to human TEF-1 (transcription enhancer factor-1)
which is required in the development of the heart (Chen et
20 al., 1994, Genes Devel. 8:2293-2301. Another (spock), is
distantly related to yeast genes encoding secretion proteins
and is important during gastrulation.

The above experiments have established that the ROSA
system is an effective analytical tool for genetic analysis
25 in mammals. However, the structure of many ROSA vectors
selects for the "trapping" of 5' exons which, in many cases,
do not encode proteins. Such a result is adequate where one
wishes to identify and eventually clone control (i.e.,
promoter or enhancer) sequences, but is not optimal where the
30 generation of insertion-inactivated null mutations is
desired, and relevant coding sequence is needed. Thus, the
construction of large-scale mutant (preferably null mutant)
libraries requires the use of vectors that have been designed
to select for insertion events that have occurred within the
35 coding region of the mutated genes as well as vectors that
are not limited to detecting insertions into expressed genes.

3.0. SUMMARY OF THE INVENTION

An object of the present invention is to provide a set of genetically altered cells (the 'Library'). The genetic alterations are of sufficient randomness and frequency such

5 that the combined population of cells in the Library represent mutations in essentially every gene found in the cell's genome. The Library is used as a source for obtaining specifically mutated cells, cell lines derived from the individually mutated cells, and cells for use in the

10 production of transgenic non-human animals.

A further object is to provide the vectors, both DNA and retroviral based, that may be used to generate the Library. Typically, at least two distinct vector designs will be used in order to mutate genes that are actively expressed in the

15 target cell, and genes that are not expressed in the target cell. Combining the mutant cells obtained using both types of vectors best ensures that the Library provides a comprehensive set of gene mutations.

A particularly useful vector class contemplated by the

20 present invention includes a vector for inserting foreign exons into animal cell transcripts that comprises a selectable marker, a promoter element operatively positioned 5' to the selectable marker, a splice donor site operatively positioned 3' to the selectable marker, and a second

25 mutagenic foreign polynucleotide sequence located upstream from the promoter element that disrupts, or otherwise "poisons", the splicing or read-through expression of the endogenous cellular transcript. Typically, the mutagenic foreign polynucleotide sequence may incorporate a

30 polyadenylation (pA) site, a nested set of stop codons in each of the three reading frames, splice acceptor and splice donor sequences in operable combination, a mutagenic exon, or any mixture of mutagenic features that effectively prevent the expression of the cellular gene. For example, a

35 polyadenylation sequence may be incorporated in addition to or in lieu of the splice donor sequence. A preferred organization for the mutagenic polynucleotide sequence

- 4 -

comprises a polyadenylation site positioned upstream from a
selectable marker which is in turn located upstream from a
splice acceptor sequence. Preferably, such a vector does not
comprise a transcription terminator or polyadenylation site
5 operatively positioned relative to the coding region of the
selectable marker, and shall not comprise a splice acceptor
site operatively positioned between the promoter element and
the initiation codon of said selectable marker.

An additional vector contemplated by the present
10 invention is designed to replace the normal 3' end of an
animal cell transcript with a foreign exon. Such a vector
shall generally be engineered to comprise a selectable
marker, a splice acceptor site operatively positioned
upstream (5') from the initiation codon of the selectable
15 marker, and a polyadenylation site operatively positioned
downstream (3') from the termination codon (3' end) of the
selectable marker. Preferably, the vector will not comprise
a promoter element operatively positioned upstream from the
coding region of the selectable marker, and will not comprise
20 a splice donor sequence operatively positioned between the 3'
end of the coding region of the selectable marker and the
polyadenylation site.

Yet another vector contemplated by the present invention
is a vector designed to insert a mutagenic foreign
25 polynucleotide sequence within an animal cell transcript
(i.e., the foreign polynucleotide sequence is flanked on both
sides by endogenous exons). As described above, the
mutagenic foreign polynucleotide sequence may be any sequence
that disrupts the normal expression of the gene into which
30 the vector has integrated. Optionally, the vector may
additionally incorporate a selectable marker, a splice
acceptor site operatively positioned 5' to the initiation
codon of the selectable marker, a splice donor site
operatively positioned 3' to said selectable marker.
35 Preferably, this vector shall not comprise a polyadenylation
site operatively positioned 3' to the coding region of said
selectable marker, and shall not comprise a promoter element

operatively positioned 5' to the coding region of said
selectable marker.

An additional embodiment of the present invention is a
library of genetically altered cells that have been treated
5 to stably incorporate one or more types of the vectors
described above.   The presently described library of
cultured animal cells may be made by a process comprising the
steps of treating (i.e., infecting, transfecting,
retrotransposing, or virtually any other method of
10 introducing polynucleotides into a cell) a population of
cells to stably integrate a vector that mediates the splicing
of a foreign exon internal to a cellular transcript,
transfecting another population of cells to stably integrate
a vector that mediates the splicing of a foreign exon 5' to
15 an exon of a cellular transcript, and selecting for
transduced cells that express the products encoded by the
foreign exons.

Alternatively, an additional embodiment of the present
invention describes a mammalian cell library made by a method
20 comprising the steps of: transfecting a population of cells
with a vector capable of expressing a selectable marker in
the cell only after the vector inserts into the host genome;
transfecting or infecting a population of cells with a vector
containing a selectable marker that is substantially only
25 expressed by cellular control sequences (after the vector
integrates into the host cells genome); and growing the
transfected cells under conditions that select for the
expression of the selectable marker.

In an additional embodiment of the present invention,
30 the two populations of transfected cells will be individually
grown under selective conditions, and the resulting mutated
population of cells collectively comprises a substantially
comprehensive library of mutated cells.

In an additional embodiment of the present invention,
35 the individual mutant cells in the library are separated and
clonally expanded. Additionally, the clonally expanded
mutant cells may then be analyzed to ascertain the DNA

sequence, or partial DNA sequence of the mutated host gene.

The presently described methods of making, organizing, and indexing libraries of mutated animal cells are also broadly applicable to virtually any eukaryotic cells that may
5 be genetically manipulated and grown in culture.

The invention provides for sequencing every gene mutated in the Library. The resulting sequence database subsequently serves as an index for the library. In essence, every cell line in the Library is individually catalogued using the
10 partial sequence information. The resulting sequence is specific for the mutated gene since the present methods are designed to obtain sequence information from exons that have been spliced to the marker sequence. Since the coverage of the mutagenesis is preferably the entire set of genes in the
15 genome, the resulting Library sequence database contains sequence from essentially every gene in the cell. From this database, a gene of interest can be identified. Once identified, the corresponding mutant cell may be withdrawn from the Library based on cross reference to the sequence
20 data.

An additional embodiment of the invention provides for methods of isolating mutations of interest from the Library. Two methods are proposed for obtaining individual mutant cell lines from the Library. The first provides a scheme where
25 clones of the cells generated using the above vectors are pooled into sets of defined size. Using the procedure described below which utilizes reverse transcription (RT) and polymerase chain reaction (PCR), a cell line with a mutation in a gene whose sequence is partly or wholly known is
30 isolated from organized sets of these pools. A few rounds of this screening procedure results in the isolation of the desired individual cell line.

A second procedure involves the sequencing of regions flanking the vector insertion sites in the various cells in
35 the library. The sequence database generated from these data effectively constitutes an index of the clones in the library that may be used to identify cells having mutations in

specific genes.

4.0. DESCRIPTION OF THE FIGURES

Figure 1.   Shows a diagrammatic representation of 5 different
5 vectors that are generally representative of the type of
vectors that may be used in the present invention.

Figure 2.   Shows a general strategy for identifying "trapped"
cellular sequences by PCR analysis of the cellular exons that
10 flank the foreign intron introduced by the VICTR 2 vector.

Figure 3 shows a PCR based strategy for identifying tagged
genes by chromosomal location.

15 Figure 4.   Is a diagrammatic representation of a strategy of
identifying or indexing the specific clones in the library
via PCR analysis and sequencing of mRNA samples obtained from
the cells in the library.

20 Figure 5.   Is a diagrammatic representation of a method of
isolating positive clones by screening pooled mutant cell
clones.

Figure 6.   Partial nucleic acid or predicted amino acid
25 sequence data from 9 clones (OST1-9) isolated using the
described techniques aligned with similar sequences from
previously characterized genes.

Figure 7.   Provides a diagrammatic representation of VICTRs 3
30 and 20 as well as the transcripts that result after
integration into a hypothetical region of the target cell
genome (i.e., "Wildtype Locus).

Figure 8.   Provides a representative list of a portion of the
35 known genes that have been identified using the disclosed
methods and technology.

5.0. DETAILED DESCRIPTION OF THE INVENTION

The present invention describes a novel indexed library
containing a substantially comprehensive set of mutations in
the host cell genome, and methods of making and using the

5 same. The presently described Library comprises as a set of
cell clones that each possess at least one mutation (and
preferably a single mutation) caused by the insertion of DNA
that is foreign to the cell. For the purposes of the present
invention, "foreign" polynucleotide sequences can be any

10 sequences that are newly introduced to a cell, do not
naturally occur in the cell at the engineered region of the
chromosome, or occur in the cell but are not organized to
provide an identical function to that provided in the
engineered vector.

15   The particularly novel features of the Library include
the methods of construction, and indexing. To index the
library, the mutant cells of the library are clonally
expanded and each mutated gene is at least partially
sequenced. The Library thus provides a novel tool for

20 assessing the specific function of a given gene. The
insertions cause a mutation which allow for essentially every
gene represented in the Library to be studied using genetic
techniques either *in vitro* or *in vivo* (via the generation of
transgenic animals). For the purposes of the present

25 invention, the term "essentially every gene" shall refer to
the statistical situation where there is generally at least
about a 70 percent probability that the genomes of cells used
to construct the library collectively contain at least one
inserted vector sequence in each gene, preferably a 85

30 percent probability, and more specifically at least about a
95 percent probability as determined by a standard Poisson
distribution.

Also for the purposes of the present invention the term
"gene" shall refer to any and all discrete coding regions of

35 the cell's genome, as well as associated noncoding and
regulatory regions. Additionally, the term operatively
positioned shall refer to the control elements or genes that

are provided with the proper orientation and spacing to
provide the desired or indicated functions of the control
elements or genes.

    For the purposes of the present invention, a gene is
5 "expressed" when a control element in the cell mediates the
production of functional or detectable levels of mRNA encoded
by the gene, or a selectable marker inserted therein. A gene
is not expressed where the control element in the cell is
absent, has been inactivated, or does not mediate the
10 production of functional or detectable levels of mRNA encoded
by the gene, or a selectable marker inserted therein.

5.1. Vectors used to build the Library

    A number of investigators have developed gene trapping
15 vectors and procedures for use in mouse and other cells
(Allen et al., 1988; Bellen et al., 1989, Genes Dev.
3(9):1288-1300; Bier et al., 1989, Genes Dev. 3(9):1273-1287;
Bonnerot et al., 1992, J Virol. 66(8):4982-4991; Brenner et
al., 1989; Chang et al., 1993; Friedrich and Soriano, 1993;
20 Friedrich and Soriano, 1991; Goff, 1987; Methods Enzymol.
152:469-481; Gossler et al.; Hope, 1991; Kerr et al., 1989;
Reddy et al., 1991; Reddy et al., 1992; Skarnes et al., 1992;
von Melchner and Ruley; Yoshida et al., 1995). The gene
trapping system described in the present invention is based
25 on significant improvements to the published SA (splice
acceptor) DNA vectors and the ROSA (reverse orientation,
splice acceptor) retroviral vectors (Chen et al., 1994;
Friedrich and Soriano, 1991 and 1993). The presently
described vectors also use a selectable marker called βgeo.
30 This gene encodes a protein which is a fusion between the β-
galactosidase and neomycin phosphotransferase proteins. The
presently described vectors place a splice acceptor sequence
upstream from the βgeo gene and a poly-adenylation signal
sequence downstream from the marker. The marker is
35 integrated after transfection by, for example,
electroporation (DNA vectors), or retroviral infection, and
gene trap events are selected based on resistance to G418

resulting from activation of *βgeo* expression by splicing from
the endogenous gene into the ROSA splice acceptor. This type
of integration disrupts the transcription unit and preferably
results in a null mutation at the locus.

5   Although gene trapping has proven a useful analytical
tool, the present invention contemplates gene trapping on a
large scale. The vectors utilized in the present invention
have been engineered to overcome the shortcomings of the
early gene trap vector designs, and to facilitate procedures
10 allowing high throughput. In addition, procedures are
described that allow the rapid and facile acquisition of
sequence information from each trapped cDNA which may be
adapted to allow complete automation. These latter
procedures are also designed for flexibility so that
15 additional molecular information can easily be obtained
subsequently. The present invention therefore incorporates
gene trapping into a larger and unique tool. A specially
organized set of gene trap clones that provide a novel and
powerful new tool of genetic analysis.

20   The presently described vectors are superficially
similar to the ROSA family of vectors, but constitute
significant improvements and provide for additional features
that are useful in the construction and indexing of the
Library. Typically, gene trapping vectors are designed to
25 detect insertions into transcribed gene regions within the
genome. They generally consist of a selectable marker whose
normal expression is handicapped by exclusion of some element
required for proper transcription. When the vector
integrates into the genome, and acquires the necessary
30 element by juxtaposition, expression of the selectable marker
is activated. When such activation occurs, the cell can
survive when grown in the appropriate selective medium which
allows for the subsequent isolation and characterization of
the trapped gene. Integration of the gene trap generally
35 causes the gene at the site of integration to be mutated.
        Some gene trapping vectors have a splice acceptor
preceding a selectable marker and a poly-adenylation signal

following the selectable marker, and the selectable marker
gene has its own initiator ATG codon. Using this
arrangement, the fusion transcripts produced after
integration generally only comprise exons 5' to the insertion
5   site to the known marker sequences. Where the vector has
inserted into the 5' region of the gene, it is often the case
that the only exon 5' to the vector is a non-coding exon.
Accordingly, the sequences obtained from such fusions do not
provide the desired sequence information about the relevant
10 gene products. This is because untranslated sequences are
generally less well conserved than coding sequences.

        To compensate for the short-comings of earlier vectors,
the vectors of the present invention have been designed so
that 3' exons are appended to the fusion transcript by
15 replacing the poly-adenylation and transcription termination
signals of earlier ROSA vectors with a splice donor (SD)
sequence. Consequently transcription and splicing generally
results in a fusion between all or most of the endogenous
transcript and the selectable marker exon, for example *βgeo*,
20 neomycin (*neo*) or puromycin (*puro*). The exon sequences
immediately 3' to the selectable marker exon may then be
sequenced and used to establish a database of expressed
sequence tags. The presently described procedures will
typically provide approximately 200 nucleotides of sequence,
25 or more. These sequences will generally be coding and
therefore informative. The prediction that the sequence
obtained will be from coding region is based on two factors.
First, gene trap vectors are generally found near the 5' end
of the gene immediately after untranslated exons because the
30 method selects for integration events that place the
initiator ATG of the selectable marker as the first
encountered, and thus used, for translation. Second,
mammalian transcripts have short 5' untranslated regions
(UTRs) which are typically between 50 and 150 nucleotides in
35 length.

        The obtained sequence information also provides a ready
source of probes that may be used to isolate the full-length

gene or cDNA from the host cell, or as heterologous probes
for the isolation of homologous genes in other species.

Internal exons in mammalian transcripts are generally
quite small, on the average 137 bases with few over 300
5 bases. Consequently, a large internal exon may be spliced
less efficiently. Thus, the presently described vectors have
been designed to sandwich relatively small selectable markers
(for example: neo ,~800 bases, or a smaller drug resistance
gene such as puro ,~600 bases) between the requisite splicing
10 elements to produce relatively small exons. Exons of this
size are more typical of mammalian exons and do not present
undue problems for the splicing machinery of the cell. Such
a design consideration is novel to the presently disclosed
gene trapping vectors. Accordingly, an additional embodiment
15 of the claimed vectors is that the respective splice acceptor
and splice donor sites are engineered such that they are
operatively positioned close to the ends of the selectable
marker coding region (the region spanning from the initiation
codon to the termination codon). Generally, the splice
20 acceptor or splice donor sequences shall appear within about
80 bases from the nearest end of the selectable marker coding
region, preferably within about 50 bases from the nearest end
of the coding region, more preferably within about 30 bases
from the nearest end of the coding regions and specifically
25 within about 20 bases of the nearest end of the selectable
marker coding region.

The new vectors are represented in retroviral form in
Figure 1. They are used by infecting target cells with
retroviral particles such that the proviruses shown in the
30 schematic can be found in the genome of the target. These
vectors are called VICTR which is an acronym for "viral
constructs for trapping".

The presently described retroviral vectors may be used
in conjunction with retroviral packaging cell lines such as
35 those described in U.S. Patent No. 5,449,614 ("'614 patent")
issued September 12, 1995, herein incorporated by reference.
Where non-mouse animal cells are to be used as targets for

generating the described libraries, packaging cells producing
retrovirus with amphotropic envelopes will generally be
employed to allow infection of the host cells.

     The mutagenic gene trap DNA may also be introduced into
5 the target cell genome by various transfection techniques
  which are familiar to those skilled in the art such as
  electroporation, lipofection, calcium phosphate
  precipitation, infection, retrotransposition, and the like.
  Examples of such techniques may be found in Sambrook *et al.*
10 (1989) Molecular Cloning Vols. I-III, Cold Spring Harbor
  Laboratory Press, Cold Spring Harbor, New York, and Current
  Protocols in Molecular Biology (1989) John Wiley & Sons, all
  Vols. and periodic updates thereof, herein incorporated by
  reference. The transfected versions of the retroviral
15 vectors are typically plasmid DNA molecules containing DNA
  cassettes comprising the described features between the
  retroviral LTRs.

     The vectors VICTR 1 and 2 (Fig. 1) are designed to trap
  genes that are transcribed in the target cell. To trap genes
20 that are not expressed in the target cell, gene trap vectors
  such as VICTR 3, 4 and 5 (described below) are provided.
  These vectors have been engineered to contain a promoter
  element capable of initiating transcription in virtually any
  cell type which is used to transcribe the coding sequence of
25 the selectable marker. However, in order to get proper
  translation of the marker product, and thus render the cell
  resistant to the selective antibiotic; a polyadenylation
  signal and a transcription termination sequence must be
  provided. Vectors VICTR 3 through 5 are constructed such
30 that an effective polyadenylation signal can only be provided
  by splicing with an externally provided downstream exon that
  contains a poly-adenylation site. Therefore, since the
  selectable marker coding region ends only in a splice donor
  sequence, these vectors must be integrated into a gene in
35 order to be properly expressed. In essence, these vectors
  append the foreign exon encoding the marker to the 5' end of
  an endogenous transcript. These events will tag genes and

create mutations that are used to make clones that will
become part of the Library.

With the above design considerations, the VICTR series
of vectors, or similarly designed and constructed vectors,
5 have the following features. VICTR 1 is a terminal exon gene
trap. VICTR 1 does not contain a control region that
effectively mediates the expression of the selectable marker
gene. Instead, the coding region of the selectable marker
contained in VICTR 1, in this case encoding puromycin
10 resistance (but which can be any selectable marker functional
in the target cell type), is preceded by a splice acceptor
sequence and followed by a polyadenylation addition signal
sequence. The coding region of the *puro* gene has an
initiator ATG which is downstream and adjacent to a region of
15 sequence that is most favorable for translation initiation in
eukaryotic cells - the so called Kozak consensus sequence
(Kozak, 1989, J. Cell, Biol. *108(2)*:229-241). With a Kozak
sequence and an initiator ATG, the *puro* gene in VICTR 1 is
activated by integrating into the intron of an active gene,
20 and the resulting fusion transcript is translated beginning
at the puromycin initiation (ATG/AUG) codon. However,
terminal gene trap vectors need not incorporate an initiator
ATG codon. In such cases, the gene trap event requires
splicing and the translation of a fusion protein that is
25 functional for the selectable marker activity. The inserted
puromycin coding sequence must therefore be translated in the
same frame as the "trapped" gene.

The splice acceptor sequence used in VICTR 1 and other
members of the VICTR series is derived from the adenovirus
30 major late transcript splice site located at the intron
1/exon 2 boundary. This sequence contains a polypyrimidine
stretch preceding the AG dinucleotide which denotes the
actual splice site. The presently described vectors
contemplate the use of any similarly derived splice acceptor
35 sequence. Preferably, the splice acceptor site will only
rarely, if ever, be involved in alternative splicing events.

The polyadenylation signal at the end of the *puro* gene
is derived from the bovine growth hormone gene. Any
similarly derived polyadenylation signal sequence could be
used if it contains the canonical AATAAA and can be
5 demonstrated to terminate transcription and cause a
polyadenylate tail to be added to the engineered coding
exons.

       VICTR 2 is a modification of VICTR 1 in which the
polyadenylation signal sequence is removed and replaced by a
10 splice donor sequence. Like VICTR 1, VICTR 2 does not
contain a control region that effectively mediates the
expression of the selectable marker gene. Typically, the
splice donor sequence to be employed in a VICTR series vector
shall be determined by reference to established literature or
15 by experimentation to identify which sequences properly
initiate splicing at the 5' end of introns in the desired
target cell. The specifically exemplified sequence,
AGGTAAGT, results in splicing occurring in between the two G
bases. Genes trapped by VICTR 2 splice upstream exons onto
20 the *puro* exon and downstream exons onto the end of the *puro*
exon. Accordingly, VICTR 2 effectively mutates gene
expression by inserting a foreign exon in-between two
naturally occurring exons in a given transcript. Again, the
puro gene may or may not contain a consensus Kozak
25 translation initiation sequence and properly positioned ATG
initiation codon. As discussed above, gene trapping by
VICTR 1 and VICTR 2 requires that the mutated gene is
expressed in the target cell line. By incorporating a splice
donor into the VICTR traps, transcript sequences downstream
30 from the gene trap insertion can be determined. As described
above, these sequences are generally more informative about
the gene mutated since they are more likely to be coding
sequences. This sequence information is gathered according
to the procedures described below.

35   VICTR 3, VICTR 4 and VICTR 5 are gene trap vectors that
do not require the cellular expression of the endogenous
trapped gene. The VICTR vectors 3 through 5 all comprise a

- 16 -

promoter element that ensures that transcription of the
selectable marker would be found in all cells that have taken
up the gene trap DNA. This transcription initiates from a
promoter, in this case the promoter element from the mouse
5 phosphoglycerate kinase (PGK) gene. However, since the
constructs lack a polyadenylation signal there can be no
proper processing of the transcript and therefore no
translation. The only means to translate the selectable
marker and get a resistant cell clone is by acquiring a
10 polyadenylation signal. Since polyadenylation is known to be
concomitant with splicing, a splice donor is provided at the
end of the selectable marker. Therefore, the only positive
gene trap events using VICTR 3 through 5 will be those that
integrate into a gene's intron such that the marker exon is
15 spliced to downstream exons that are properly polyadenylated.
Thus genes mutated with the VICTR vectors 3 through 5 need
not be expressed in the target cell, and these gene trap
vectors can mutate all genes having at least one intron. The
design of VICTR vectors 3 through 5 requires a promoter
20 element that will be active in the target cell type, a
selectable marker and a splice donor sequence. Although a
specific promoter was used in the specific embodiments, it
should be understood that appropriate promoters may be
selected that are known to be active in a given cell type.
25 Typically, the considerations for selecting the splice donor
sequence are identical to those discussed for VICTR 2, *supra*.
     VICTR 4 differs from VICTR 3 only by the addition of a
small exon upstream from the promoter element of VICTR 4.
This exon is intended to stop normal splicing of the mutated
30 gene. It is possible that insertion of VICTR 3 into an
intron might not be mutagenic if the gene can still splice
between exons, bypassing the gene trap insertion. The exon
in VICTR 4 is constructed from the adenovirus splice acceptor
described above and the synthetic splice donor also described
35 above. Stop codons are placed in all three reading frames in
the exon, which is about 100 bases long. The stops would
truncate the endogenous protein and presumably cause a

mutation.

A conceptually similar alternative design uses a
terminal exon like that engineered into VICTR 5. Instead of
a splice donor, a polyadenylation site is used to terminate

5 transcription and produce a truncated message. Stops in all
three frames are also provided to truncate the endogenous
protein as well as the resulting transcript.

VICTR 20 is a modified version of VICTR 3 that
incorporates a polyadenylation site 5' to the PGK promoter,

10 the IRESβgeo sequence (i.e., foreign mutagenic polynucleotide
sequence) 5' to the polyadenylation site, and a splice
acceptor site 5' to the IRESβgeo coding region. VICTR 20
additionally incorporates, in operable combination, a pair of
recombinase recognition sites that flank the PGKpuroSD

15 cassette.

All of the traps of the VICTR series are designed such
that a fusion transcript is formed with the trapped gene.
For all but VICTR 1, the fusion contains cellular exons that
are located 3' to the gene trap insertion. All of the

20 flanking exons may be sequenced according to the methods
described in the following section. To facilitate
sequencing, specific sequences are engineered onto the ends
of the selectable marker (e.g., puromycin coding region).
Examples of such sequences include, but are not limited to

25 unique sequences for priming PCR, and sequences complementary
to the standard M13 forward sequencing primer. Additionally,
stop codons are added in all three reading frames to ensure
that no anomalous fusion proteins are produced. All of the
unique 3' primer sequences are followed immediately by the

30 synthetic 9 base pair splice donor sequence. This keeps the
size of the exon comprising the selectable marker (puro gene)
at a minimum to best ensure proper splicing, and positions
the amplification and sequencing primers immediately adjacent
to the flanking "trapped" exons to be sequenced as part of

35 the construction of a Library database.

When any members of the VICTR series are constructed as
retroviruses, the direction of transcription of the

selectable marker is opposite to that of the direction of the
normal transcription of the retrovirus. The reason for this
organization is that the transcription elements such as the
polyadenylation signal, the splice sites and the promoter
5 elements found in the various members of the VICTR series
interfere with the proper transcription of the retroviral
genome in the packaging cell line. This would eliminate or
significantly reduce retroviral titers. The LTRs used in the
construction of the packaging cell line are self-
10 inactivating. That is, the enhancer element is removed from
the 3' U3 sequences such that the proviruses resulting from
infection would not have an enhancer in either LTR. An
enhancer in the provirus may otherwise affect transcription
of the mutated gene or nearby genes.
15   Since a 'cryptic' splice donor sequence is found in the
inverted LTRs, this splice donor sequence has been removed
from the VICTR vectors by site specific mutagenesis. It was
deemed necessary to remove this splice donor so that it would
not affect the trapping splicing events.
20   The present disclosure also describes vectors that
incorporate a new way to conduct positive selection. VICTR 3
and VICTR 20 are two examples of such vectors. Both VICTR 3
and VICTR 20, contain PGKpuroSD which must splice into exons
of gene that provide a polyadenylation addition sequence in
25 order to allow expression of the puromycin selectable marker
gene. When placed in a targeting vector, PGKpuroSD allows
for positive selection when targeting takes place. In
addition to providing positive selection, targeted events
among resistant colonies are easy to identify by the 3' RACE
30 protocols (see section 5.2.2., *infra*) used for Omnibank
production. This automated process allows for the rapid
identification of targeted events. It is important that
unlike SAβgeo, PGKpuroSD does not require expression of the
targeted gene in order to provide positive selection. In
35 addition, VICTR 20 provides 2 potential positive selectable
markers (puro and neo). The use of two selectable markers,
when a gene is expressed, provides a means to increase the

targeting efficiency by requiring both selectable markers to
function which is much more remote a possibility than having
one selectable marker function unless there is a targeted
event. The addition of a negative selection cassette to
5 these vectors would only increase their targeting efficiency.

An additional feature that may be incorporated into the
presently described vectors includes the use of recombinase
recognition sequences. Bacteriophage P1 Cre recombinase and
flp recombinase from yeast plasmids are two examples of
10 site-specific DNA recombinase enzymes which cleave DNA at
specific target sites (loxP sites for cre recombinase and frt
sites for flp recombinase) and catalyze a ligation of this
DNA to a second cleaved site. When a piece of DNA is flanked
by 2 loxP or frt sites (e.g., recombinase control elements)
15 in the same orientation, the corresponding recombinase will
cause the removal of the intervening DNA sequence. When a
piece of DNA is flanked by loxP or frt sites in an indirect
orientation, the corresponding recombinase will essentially
activate the control elements to cause the intervening DNA to
20 be flipped into the opposite orientation. These recombinases
provide powerful approaches for manipulating DNA *in situ*.

Recombinases have important applications for gene
trapping and the production of a library of trapped genes.
When constructs containing PGKpuroSD are used to trap genes,
25 the fusion transcript between puromycin and sequences of the
trapped gene could result in some level of protein expression
from the trapped gene if translational reinitiation occurs.
Another important issue is that several reports suggest that
the PGK promoter can affect the expression of nearby genes.
30 These effects may make it difficult to determine gene
function after a gene trap event since one could not discern
whether a given phenotype is associated with the inactivation
of a gene, or the transcription of nearby genes. Both
potential problems are solved by exploiting recombinase
35 activity. When PGKpuroSD is flanked by loxP, frt, or any
other recombinase sites in the same orientation, the addition
of the corresponding recombinase will result in the removal

of PGKpuroSD. In this way, effects caused by PGKpuroSD
fusion transcripts, or the PGK promoter, are avoided.

　　　Accordingly, a vector that may be particularly useful
for the practice of the present invention is VICTR 20. This
5 vector replaces the terminal exon of VICTR 5 with a splice
acceptor located upstream from the βgeo gene which can be
used for both LacZ staining and antibiotic selection. The
fusion gene possesses its own initiator methionine and an
internal ribosomal entry site (IRES) for efficient
10 translation initiation. In addition, the PGK promoter and
puromycin-splice donor sequences have been flanked by lox P
recombination sites. This allows for the ability to both
remove and introduce sequences at the integration site and is
of potential value with regard to the manipulation of regions
15 proximal to trapped target genes (Barinaga, Science 265:26-8,
1994). While this particular vector includes lox P
recombination sites, the present invention is in no way
limited to the use of this specific recombination site (Akagi
et al., Nucleic Acids Res 25:1766-73, 1997).

20 　　　Another very important use of recombinases is to produce
mutations that can be made tissue-specific and/or inducible.
In the presently described vectors, the Saβgeo or SAIRESβgeo
component provides the mutagenic function by "trapping" the
normal splicing from preceding exons. If the SAβgeo is
25 flanked by inverted loxP, frt, or any other recombinase
sites, the addition of the corresponding recombinase results
in the flipping of the SAβgeo sequence so that it no longer
prevents the normal splicing of the cellular gene into which
it is integrated. To make a gene trap tissue-specific or
30 inducible one could produce the trap with SAβgeo in the
reverse orientation and then provide recombinase activity
only at the time and place where one wishes to remove the
gene function. The use of tissue-specific or inducible
recombinase constructs allows one to choose when and where
35 one removes, or activates, the function of the targeted gene.

　　　One method for practicing the inducible forms of
recombinase mediated gene expression involves the use of

vectors that use inducible or tissue specific
promoter/operator elements to express the desired recombinase
activity. The inducible expression elements are preferably
operatively positioned to allow the inducible control or
5 activation of expression of the desired recombinase activity.
Examples of such inducible promoters or control elements
include, but are not limited to, tetracycline,
metallothionine, ecdysone, and other steroid-responsive
promoters, rapamycin responsive promoters, and the like (No
10 et al., Proc Natl Acad Sci USA 93:3345-51, 1996; Furth et
al., Proc Natl Acad Sci USA 91:9302-6, 1994). Additional
control elements that can be used include promoters requiring
specific transcription factors such as viral, particularly
HIV, promoters. Vectors incorporating such promoters would
15 only express recombinase activity in cells that express the
necessary transcription factors.

The incorporation of recombinase sites into the gene
trapping vectors highlights the value of using the described
gene trap vectors to deliver specific DNA sequence elements
20 throughout the genome. Although a variety of vectors are
available for placing sequences into the genome, the
presently described vectors facilitate both the insertion of
the specific elements, and the subsequent identification of
where sequence has inserted into the cellular chromosome.
25 Additionally, the presently described vectors may be used to
place recombinase recognition sites throughout the genome.
The recombinase recognition sites could then be used to
either remove or insert specific DNA sequences at
predetermined locations.
30   Moreover, the described gene trap vectors can also be
used to insert regulatory elements throughout the genome.
Recent work has identified a number of inducible or
repressible systems that function in the mouse. These
include the rapamycin, tetracycline, ecdysone,
35 glucocorticoid, and heavy metal inducible systems. These
systems typically rely on placing DNA elements in or near a
promoter. An inducible or repressible transcription factor

- 22 -

that can identify and bind to the DNA element may also be
engineered into the cells. The transcription factor will
specifically bind to the DNA element in either the presence
or absence of a ligand that binds to the transcription factor
5   and, depending on the structure of the transcription factor,
it will either induce or repress the expression of the
cellular gene into which the DNA elements have been inserted.
The ability to place these inducible or repressible elements
throughout the genome would increase the value of the library
10 by adding the potential to regulate the expression of the
trapped gene.

        The vectors described also have important applications
for the overexpression of genes or portions of genes to
select for phenotypic effects. Currently, overexpression of
15 cDNA libraries to look for genes or parts of genes with
specific functions is a common practice. One example would
be to overexpress genes or portions of genes to look for
expression that causes loss of contact inhibition for cell
growth as determined by growth in soft agar. This would
20 allow the identification of genes or portions of genes that
can act as oncogenes. Simple modifications of VICTR 20 would
allow it to be used for these applications. For example, the
addition of an internal ribosome entry site (IRES) 3' to the
puromycin selectable marker and before the SD sequence, would
25 result in the overexpression of sequences from the trapped
downstream exons. In addition, the IRES could be modified
by, for example, the addition of one or two nucleotides such
that there could be 3 basic vectors that would allow
expression of trapped exons in all three reading frames. In
30 this way, genes could be trapped throughout the genome
resulting in overexpression of genes, or portions thereof, to
examine the cellular function of the trapped genes. This
identification of function could be done by selecting for the
function of interest (i.e., growth in soft agar could result
35 from the overexpression of potentially oncogenic genes).
This technique would allow for the screening or selection of
large numbers of genes, or portions thereof, by

overexpressing the genes and identifying cells displaying the phenotypes of interest. Additional assays could, for example, identify candidate tumor suppressor genes based on their ability, when overexpressed, to prevent growth in soft
5 agar.

Given the fact that expression pattern information can provide insight into the possible functions of genes mutated by the current methods, another LTR vector, VICTR 6, has been constructed in a manner similar to VICTR 5 except that the
10 terminal exon has been replaced with either a gene coding for β-galactosidase (βgal) or a fusion between β-gal and neomycin phosphotransferase (βgeo), each proceeded by a splice acceptor and followed by a polyadenylation signal. Endogenous gene expression and splicing of these markers into
15 cellular transcripts and translation into fusion proteins will allow for increased mutagenicity as well as the delineation of expression through Lac Z staining.

An additional vector, VICTR 12, incorporates two separate selectable markers for the analysis of both
20 integration sites and trapped genes. One selectable marker (e.g. puro) is similar to that for VICTRs 3 through 5 in that it contains a promoter element at its 5' end and a splice donor sequence 3'. This gene cassette is located in the LTRs of the retroviral vector. The other marker (neo) also
25 contains a promoter element but has a polyadenylation signal present at the 3' end of the coding sequence and is positioned between the viral LTRs. Both selectable markers contain an initiator ATG for proper translation. The design of VICTR 12 allows for the assessment of absolute titer as
30 assayed by the number of colonies resistant to antibiotic selection for the constitutively expressed marker possessing a polyadenylation signal. This titer can then be compared to that observed for gene-trapping and stable expression of the resistance marker flanked at its 3' end by a splice donor.
35 These numbers are important for the calculation of gene trapping frequency in the context of both nonspecific binding by retroviral integrase and directed binding by chimeric

- 24 -

integrase fusions. In addition, it provides an option to
focus on the actual integration sites through infection and
selection for the marker containing the polyadenylation
signal. This eliminates the need for the fusion protein
5 binding to occur upstream and in the proximity of the target
gene. Theoretically, any transcription factor binding sites
present within the genome are targets for proximal
integration and subsequent antibiotic resistance. Analysis
of sequences flanking the LTRs of the retroviral vector
10 should reveal canonical factor binding sites. In addition,
by including the promoter/splice donor design of VICTR 3,
gene-trapping abilities are retained in VICTR 12.

VICTR A is a vector which does not contain gene trapping
constructs but rather a selectable marker possessing all of
15 the required entities for constitutive expression including,
but not limited to, a promoter element capable of driving
expression in eukaryotic cells and a polyadenylation and
transcriptional terminal signal. Similar to VICTR 12,
downstream gene trapping is not necessary for successful
20 selection using VICTR A. This vector is intended solely to
select for successful integrations and serves as a control
for the identification of transcription factor binding sites
flanking the integrant as mentioned above.

Finally, VICTR B is similar to VICTR A in that it
25 comprises a constitutively expressed selectable marker, but
it also contains the bacterial β-lactamase ampicillin
resistance selectable marker and a ColE1 origin of
replication. These entities allow for the rapid cloning of
sequences flanking the long terminal repeats through
30 restriction digestion of genomic DNA from infected cells and
ligation to form plasmid molecules which can be rescued by
bacterial transformation, and subsequently sequenced. This
vector allows for the rapid analysis of cellular sequences
that contain putative binding sites for the transcription
35 factor of interest.

Other vector designs contemplated by the present
invention are engineered to include an inducible regulatory

elements such as tetracycline, ecdysone, and other steroid-
responsive promoters (No et al., Proc Natl Acad Sci USA
<u>93</u>:3345-51, 1996; Furth et al., Proc Natl Acad Sci USA
<u>91</u>:9302-6, 1994). These elements are operatively positioned
5 to allow the inducible control of expression of either the
selectable marker or endogenous genes proximal to site of
integration. Such inducibility provides a unique tool for
the regulation of target gene expression.

All of the gene trap vectors of the VICTR series, with
10 the exception of VICTRs A and B, are designed to form a
fusion transcript between vector encoded sequence and the
trapped target gene. All of the flanking exons may be
sequenced according to the methods described in the following
section. To facilitate sequencing, specific sequences are
15 engineered onto the ends of the selectable marker (e.g.,
puromycin coding region). Examples of such sequences
include, but are not limited to unique sequences for priming
PCR, and sequences complementary to standard M13 sequencing
primers. Additionally, stop codons are added in all three
20 reading frames to ensure that no anomalous fusion proteins
are produced. All of the unique 3' primer sequences are
immediately followed by a synthetic 9 base pair splice donor
sequence. This keeps the size of the exon comprising the
selectable marker at a minimum to ensure proper splicing, and
25 positions the amplification and sequencing primers
immediately adjacent to the flanking trapped exons to be
sequenced as part of the generation of the collection of
cells representing mutated transcription factor targets.

Since a cryptic splice donor sequence is found in the
30 inverted LTRs, this cryptic splice donor sequence has been
removed from the VICTR vectors by site specific mutagenesis.
It was deemed necessary to remove this splice donor so that
it would not affect trapping associated splicing events.

When any members of the VICTR series are packaged into
35 infectious virus, the direction of transcription of the
selectable marker is opposite to that of the direction of the
normal transcription of the retrovirus. The reason for this

organization is that the regulatory elements such as the
polyadenylation signal, the splice sites and the promoter
elements found in the various members of the VICTR series can
interfere with the transcription of the retroviral genome in
5 the packaging cell line. This potential interference may
significantly reduce retroviral titers.

     Although specific gene trapping vectors have been
discussed at length above, the invention is by no means to be
limited to such vectors. Several other types of vectors that
10 may also be used to incorporate relatively small engineered
exons into a target cell transcripts include, but are not
limited to, adenoviral vectors, adenoassociated virus
vectors, SV40 based vectors, and papilloma virus vectors.
Additionally, DNA vectors may be directly transferred into
15 the target cells using any of a variety of biochemical or
physical means such as lipofection, chemical transfection,
retrotransposition, electroporation, and the like.

     Although, the use of specific selectable markers has
been disclosed and discussed herein, the present invention is
20 in no way limited to the specifically disclosed markers.
Additional markers (and associated antibiotics) that are
suitable for either positive or negative selection of
eukaryotic cells are disclosed, *inter alia*, in Sambrook *et
al.* (1989) <u>Molecular Cloning</u> Vols. I-III, Cold Spring Harbor
25 Laboratory Press, Cold Spring Harbor, New York, and <u>Current
Protocols in Molecular Biology</u> (1989) John Wiley & Sons, all
Vols. and periodic updates thereof, as well as Table I of
U.S. Patent No. 5,464,764 issued November 7, 1995, the
entirety of which is herein incorporated by reference. Any
30 of the disclosed markers, as well as others known in the art,
may be used to practice the present invention.

5.2. The Analysis of Mutated Genes and Transcripts

     The presently described invention allows for large-scale
35 genetic analysis of the genomes of any organism for which
there exists cultured cell lines. The Library may be
constructed from any type of cell that can be transfected by

standard techniques or infected with recombinant retroviral
vectors.

    Where mouse ES cells are used, then the Library becomes
a genetic tool able to completely represent mutations in
5 essentially every gene of the mouse genome. Since ES cells
can be injected back into a blastocyst and become
incorporated into normal development and ultimately the germ
line, the cells of the Library effectively represent a
complete panel of mutant transgenic mouse strains (see
10 generally, U.S. Patent No. 5,464,764 issued November 7, 1995,
herein incorporated by reference).

    A similar methodology may be used to construct virtually
any non-human transgenic animal (or animal capable of being
rendered transgenic). Such nonhuman transgenic animals may
15 include, for example, transgenic pigs, transgenic rats,
transgenic rabbits, transgenic cattle, transgenic goats, and
other transgenic animal species, particularly mammalian
species, known in the art. Additionally, bovine, ovine, and
porcine species, other members of the rodent family, e.g.
20 rat, as well as rabbit and guinea pig and non-human primates,
such as chimpanzee, may be used to practice the present
invention.

    Transgenic animals produced using the presently
described library and/or vectors are useful for the study of
25 basic biological processes and diseases including, but not
limited to, aging, cancer, autoimmune disease, immune
disorders, alopecia, glandular disorders, inflammatory
disorders, diabetes, arthritis, high blood pressure,
atherosclerosis, cardiovascular disease, pulmonary disease,
30 degenerative diseases of the neural or skeletal systems,
Alzheimer's disease, Parkinson's disease, asthma,
developmental disorders or abnormalities, infertility,
epithelial ulcerations, and microbial pathogenesis (a
relatively comprehensive review of such pathogens is
35 provided, *inter alia*, in Mandell *et al.*, 1990, "Principles
and Practice of Infectious Disease" 3rd. ed., Churchill
Livingstone Inc., New York, N.Y. 10036, herein incorporated

by reference). As such, the described animals and cells are
particularly useful for the practice of functional genomics.

5.2.1. Constructing a Library of Individually Mutated Cell Clones

The vectors described in the previous section
were used to infect (or transfect) cells in culture, for
example, mouse embryonic stem (ES) cells. Gene trap
insertions were initially identified by antibiotic resistance
(e.g., puromycin). Individual clones (colonies) were moved
from a culture dish to individual wells of a multi-welled
tissue culture plate (e.g. one with 96 wells). From this
platform, the clones were be duplicated for storage and
subsequent analysis. Each multi-well plate of clones was
then processed by molecular biological techniques described
in the following section in order to derive sequence of the
gene that has been mutated. This entire process is presented
schematically in Figure 4 (described below).

5.2.2. Identifying and Sequencing the Tagged Genes in the Library.

The relevant nucleic acid (and derived amino
acid sequence information) will largely be obtained using
PCR-based techniques that rely on knowing part of the
sequence of the fusion transcripts (see generally, Frohman *et
al.*, 1988, Proc. Natl. Acad. Sci. U.S.A. *85(23)*:8998-9000,
and U.S. Patents Nos. 4,683,195 to Saiki *et al.*, and
4,683,202 to Mullis, which are herein incorporated by
reference). Typically, such sequences are encoded by the
foreign exon containing the selectable marker. The procedure
is represented schematically in Figure 2 (3' RACE). Although
each step of the procedure may be done manually, the
procedure is also designed to be carried out using robots
that can deliver reagents to multi well culture plates (e.g.,
but not limited to, 96-well plates).

The first step generates single stranded complementary
DNA which is used in the PCR amplification reaction (Figure

2). The RNA substrate for cDNA synthesis may either be total
cellular RNA or an mRNA fraction; preferably the latter.
mRNA was isolated from cells directly in the wells of the
tissue culture dish. The cells were lysed and mRNA was bound
5 by the complementary binding of the poly-adenylate tail to a
poly-thymidine-associated solid matrix. The bound mRNA was
washed several times and the reagents for the reverse
transcription (RT) reaction were added. cDNA synthesis in
the RT reaction was initiated at random positions along the
10 message by the binding of a random sequence primer (RS).
This RS primer has approximately 6-9 random nucleotides at
the 3' end to bind sites in the mRNA to prime cDNA synthesis,
and a 5' tail sequence of known composition to act as an
anchor for PCR amplification in the next step. There is
15 therefore no specificity for the trapped message in the RT
step. Alternatively, a poly-dT primer appended with the
specific sequences for the PCR may be used. Synthesis of the
first strand of the cDNA initiates at the end of each trapped
gene. At this point in the procedure, the bound mRNA may be
20 stored (at between about -70° C and about 4° C) and reused
multiple times. Such storage is a valuable feature where one
subsequently desires to analyze individual clones in more
detail. The bound mRNA may also be used to clone the entire
transcript using PCR-based protocols.

25   Specificity for the trapped, fusion transcript is
introduced in the next step, PCR amplification. The primers
for this reaction are complementary to the anchor sequence of
the RS primer and to the selectable marker. Double stranded
fragments between a fixed point in the selectable marker gene
30 and various points downstream in the appended transcript
sequence are amplified. It is these fragments which will
become the substrates for the sequencing reaction. The
various end-points along the transcript sequence were
determined by the binding of the random primer during the RT
35 reaction. These PCR products were diluted into the
sequencing reaction mix, denatured and sequenced using a
primer specific for the splice donor sequences of the gene

trap exon. Although, standard radioactively labeled
nucleotides may be used in the sequencing reactions,
sequences will typically be determined using standard dye
terminator sequencing in conjunction with automated
5 sequencers (e.g., ABI sequencers and the like).

Several fragments of various sizes may serve as
substrates for the sequencing reactions. This is not a
problem since the sequencing reaction proceeds from a fixed
point as defined by a specific primer sequence. Typically,
10 approximately 200 nucleotides of sequence were obtained for
each trapped transcript. For the PCR fragments that are
shorter than this, the sequencing reaction simply 'falls off'
the end. Sequences further 3' were then covered by the
longer fragments amplified during PCR. One problem is
15 presented by the anchor sequences 'S' derived from the RS
primer. When these are encountered during the sequencing of
smaller fragments, they register as anomalous dye signals on
the sequencing gels. To circumvent this potential problem, a
restriction enzyme recognition site is included in the S
20 sequence. Digestion of the double stranded PCR products with
this enzyme prior to sequencing eliminates the heterologous S
sequences.

5.2.3.   Identifying the Tagged Genes by Chromosomal Location

25   Any individually tagged gene may also be
identified by PCR using chromosomal DNA as the template. To
find an individual clone of interest in the Library arrayed
as described above, genomic DNA is isolated from the pooled
30 clones of ES cells as presented in Figure 3. One primer for
the PCR is anchored in the gene trap vector, e.g., a *puro*
exon-specific oligonucleotide. The other primer is located
in the genomic DNA of interest. This genomic DNA primer may
consist of either (1) DNA sequence that corresponds to the
35 coding region of the gene of interest, or (2) DNA sequence
from the locus of the gene of interest. In the first case,
the only way that the two primers used may be juxtaposed to

give a positive PCR results (e.g., the correct size double-
stranded DNA product) is if the gene trap vector has inserted
into the gene of interest. Additionally, degenerate primers
may be used, to identify and isolate related genes of

5   interest. In the second case, the only way that the two
primers used may be juxtaposed to provide the desired PCR
result is if the gene trap vector has inserted into the
region of interest that contains the primer for the known
marker.

10   For example, if one wishes to obtain ES cell clones from
the library that contain mutated genes located in a certain
chromosomal position, PCR primers are designed that
correspond to the *puro* gene (the puro-anchored primer) and a
primer that corresponds to a marker known to be located in

15 the region of interest. Several different combinations of
marker primers and primers that are located in the region of
interest may also be used to obtain optimum results. In this
manner, the mutated genes are identified by virtue of their
location relative to sets of known markers. Genes in a

20 particular chromosomal region of interest could therefore be
identified. The marker primers could also be designed
correspond to sequences of known genes in order to screen for
mutations in particular genes by PCR on genomic DNA
templates. While this method is likely to be less

25 informative than the RT-PCR strategy described below, this
technique would be useful as a alternative strategy to
identify mutations in known genes. In addition, primers that
correspond to sequence of known genes could be used in PCR
reactions with marker-specific primers in order to identify

30 ES cell clones that contain mutations in genes proximal to
the known genes. The sensitivity of detection is adequate to
find such events when positive clones are subsequently
identified as described below in the RT-PCR strategy.

35 **5.3. A Sequence Database Identifies Genes Mutated in the
    Library.**

    Using the procedures described above, approximately 200

to about 600 bases of sequence from the cellular exons
appended to the selectable marker exon (e.g., *puro* exon in
VICTR vectors) may be identified. These sequences provide a
means to identify and catalogue the genes mutated in each
5 clone of the Library. Such a database provides both an index
for the presently disclosed libraries, and a resource for
discovering novel genes. Alternatively, various comparisons
can be made between the Library database sequences and any
other sequence database as would be familiar to those
10 practiced in the art.

      The novel utility of the Library lies in the ability for
a person to search the Library database for a gene of
interest based upon some knowledge of the nucleic acid or
amino acid sequence. Once a sequence is identified, the
15 specific clone in the Library can be accessed and used to
study gene function. This is accomplished by studying the
effects of the mutation both *in vitro* and *in vivo*. For
example, cell culture systems and animal models (i.e.,
transgenic animals) may be directly generated from the cells
20 found in the Library as will be familiar to those practiced
in the art.

      Additionally, the sequence information may be used to
generate a highly specific probe for isolating both genomic
clones from existing data bases, as well as a full length
25 cDNA. Additionally, the probe may be used to isolate the
homologous gene from sufficiently related species, including
humans. Once isolated, the gene may be over expressed, or
used to generate a targeted knock-out vector that may be used
to generate cells and animals that are homozygous for the
30 mutation of interest. Such animals and cells are deemed to
be particularly useful as disease models (i.e., cancer,
genetic abnormalities, AIDS, etc.), for developmental study,
to assay for toxin susceptibility or the efficacy of
therapeutic agents, and as hosts for gene delivery and
35 therapy experiments (e.g., experiments designed to correct a
specific genetic defect *in vivo*).

5.4. Accessing Clones in the Library by a Pooling and Screening Procedure.

An alternative method of accessing individual clones is by searching the Library database for sequences in order to isolate a clone of interest from pools of library clones. The Library may be arrayed either as single clones, each with different insertions, or as sets of pooled clones. That is, as many clones as will represent insertions into essentially every gene in the genome are grown in sets of a defined number. For example, 100,000 clones can be arrayed in 2,000 sets of 50 clones. This can be accomplished by titrating the number of VICTR retroviral particles added to each well of 96-well tissue culture plates. Two thousand clones will fit on approximately 20 such plates. The number of clones may be dictated by the estimated number of genes in the genome of the cells being used. For example, there are approximately 100,000 genes in the genome of mouse ES cells. Therefore, a Library of mutations in essentially every gene in the mouse genome may be arrayed onto 20 96-well plates.

To find an individual clone of interest in the Library arrayed in this manner, reverse transcription-polymerase chain reactions (RT-PCR) are performed on mRNA isolated from pooled clones as presented in Figure 4. One primer for RT-PCR is anchored in the gene trap vector, i.e. a *puro* exon-specific oligonucleotide. The other primer is located in the cDNA sequence of a gene of interest. The only way that these two sequences can be juxtaposed to give a positive RT-PCR result (i.e. double stranded DNA fragment visible by agarose gel electrophoresis, as will be familiar to anyone practiced in the art) is by being present in a transcript from a gene trap event occurring in the gene of interest.

For example, if one wishes to obtain an ES cell clone with a mutation in the p53 gene, PCR primers are designed that correspond to the *puro* and p53 genes. If a VICTR trapping vector integrates into the p53 locus and results in the formation of a fusion mRNA, this mRNA may be detected by RT-PCR using these specifically designed primer pairs. The

sensitivity of detection is adequate to find such an event
when positive cells are mixed with a large background of
negative cells. The individual positive clones are
subsequently identified by first locating the pool of 50
5 clones in which it resides. This process is described in
Figure 5. The positive pool, once identified, is
subsequently plated at limiting dilution (approximately 0.3
cells/well) such that individual clones may be isolated. To
find the one positive event in 50 clones represented by this
10 pool, individual clones are isolated and arrayed on a 96-well
plate. By pooling in columns and rows, the positive well
containing the positive clone can be identified with
relatively few RT-PCR reactions.

       In addition to RT-PCR, the pools may be screened by
15 hybridization techniques (see generally Sambrook et al.,
1989, Molecular Cloning: H Laboratory Manual 2nd edition,
Cold Spring Harbor Press, Cold Spring Harbor, and Current
Protocols in Molecular Biology, 1995, Ausubel et al. eds.,
John Wiley and Sons). Specific PCR fragments are generated
20 from the mutated genes essentially as described above for the
sequencing protocols of the individual clones (first-strand
synthesis using RT primed by a random or oligo dT primer that
is appended to a specific primer binding site). The gene
trap DNA is amplified from the primer sets in the puro gene
25 and the specific sequences appended to the RT primer. If
this were done with pools, the resulting pooled set of
amplified DNA fragments could be arrayed on membranes and
probed by radioactive, or chemically or enzymatically
labeled, hybridization probes specific for a gene of
30 interest. A positive radioactive result indicates that the
gene of interest has been mutated in one of the clones of the
positively-labeled pool. The individual positive clone is
subsequently identified by PCR or hybridization essentially
as outlined above.

35   Alternatively, a similar strategy may be used to
identify the clone of interest from multiple plates, or any
scheme where a two or three dimensional array (e.g., columns

and rows) of individual clones are pooled by row or by
column. For example, 96 well plates of individual clones may
be arranged adjacent to each other to provide a larger (or
virtual/figurative) two dimensional grid (e.g., four plates
5 may be arranged to provide a net 16x24 grid), and the various
rows and columns of the larger grid may be pooled to achieve
substantially the same result.

Similarly, plates may simply be stacked, literally or
figuratively, or arranged into a larger grid and stacked to
10 provide three dimensional arrays of individual clones.
Representative pools from all three planes of the three
dimensional grid may then be analyzed, and the three positive
pools/planes may be aligned to identify the desired clone.
For example, ten 96 well plates may be screened by pooling
15 the respective rows and columns from each plate (a total of
20 pools) as well as pooling all of the clones on each
specific plate (10 additional pools). Using this method, one
may effectively screen 960 clones by performing PCR on only
30 pooled samples.

20   The example provided below is merely illustrative of the
subject invention. Given the level of skill in the art, one
may be expected to modify any of the above or following
disclosure to produce insubstantial differences from the
specifically described features of the present invention. As
25 such, the following example is provided solely by way of
illustration and is not included for the purpose of limiting
the invention in any way whatsoever.

6.0. EXAMPLES

30 6.1. Use of VICTR Series Vectors to Construct a Mouse ES cell
Gene Trap Library

VICTR 3 was used to gather a set of gene trap clones. A
plasmid containing the VICTR 3 cassette was constructed by
conventional cloning techniques and designed to employ the
35 features described above. Namely, the cassette contained a
PGK promoter directing transcription of an exon that encodes
the *puro* marker and ends in a canonical splice donor

sequence. At the end of the puromycin exon, sequences were
added as described that allow for the annealing of two nested
PCR and sequencing primers. The vector backbone was based on
pBluescript KS+ from Stratagene Corporation.

5   The plasmid construct linearized by digestion with Sca I
which cuts at a unique site in the plasmid backbone. The
plasmid was then transfected into the mouse ES cell line
AB2.2 by electroporation using a BioRad Genepulser apparatus.
After the cells were allowed to recover, gene trap clones
10 were selected by adding puromycin to the medium at a final
concentration of 3 μg/mL. Positive clones were allowed to
grow under selection for approximately 10 days before being
removed and cultured separately for storage and to determine
the sequence of the disrupted gene.

15   Total RNA was isolated from an aliquot of cells from
each of 18 gene trap clones chosen for study. Five
micrograms of this RNA was used in a first strand cDNA
synthesis reaction using the "RS" primer. This primer has
unique sequences (for subsequent PCR) on its 5' end and nine
20 random nucleotides or nine T (thymidine) residues on it's 3'
end. Reaction products from the first strand synthesis were
added directly to a PCR with outer primers specific for the
engineered sequences of puromycin and the "RS" primer. After
amplification, an aliquot of reaction products were subject
25 to a second round of amplification using primers internal, or
nested, relative to the first set of PCR primers. This
second amplification provided more reaction product for
sequencing and also provided increased specificity for the
specifically gene trapped DNA.

30   The products of the nested PCR were visualized by
agarose gel electrophoresis, and seventeen of the eighteen
clones provided at least one band that was visible on the gel
with ethidium bromide staining. Most gave only a single band
which is an advantage in that a single band is generally
35 easier to sequence. The PCR products were sequenced directly
after excess PCR primers and nucleotides were removed by
filtration in a spin column (Centricon-100, Amicon). DNA was

added directly to dye terminator sequencing reactions
(purchased from ABI) using the standard M13 forward primer a
region for which was built into the end of the *puro* exon in
all of the PCR fragments. Thirteen of the seventeen clones
5 that gave a band after the PCR provided readable sequence.
The minimum number of readable nucleotides was 207 and some
of the clones provided over 500 nucleotides of useful
sequence.

Sample data from this set of clones is presented in
10 Figure 6. Only a portion of sequence (nucleotide or putative
amino acid) for 9 Library clones obtained by the methods
described in this invention are presented. Under each
sequence fragment in the figure is aligned a homologous
sequence that was identified using the BLAST (basic local
15 alignment search tool) search algorithm (Altschul *et al.*,
1990, J. Mol. Biol. *215*:403-410).

In addition to known sequences, many new genes were also
identified. Each of these sequences is labeled "OST" for
"Omnibank Sequence Tags." OMNIBANK™ shall be the trademark
20 name for the Libraries generated using the disclosed
technology.

These data demonstrate that the VICTR series vectors may
efficiently trap genes, and that the procedures used to
obtain sequence are reliable. With simple optimization of
25 each step, it is presently possible to mutate every gene in a
given population of cells, and obtain sequence from each of
these mutated genes. The sample data provided in this
example represents a small fraction of an entire Library. By
simply performing the same procedures on a larger scale (with
30 automation) a Library may be constructed that collectively
comprises and indexes mutations in essentially every gene in
the genome of the target cell.

Additional studies have used both VICTR 3 and VICTR 20.
Like VICTR 3, VICTR 20 is exemplary of a family of vectors
35 that incorporate two main functional units: a sequence
acquisition component having a strong promoter element
(phosphoglycerate kinase 1) active in ES cells that is fused

to the puromycin resistance gene coding sequence which lacks
a polyadenylation sequence but is followed by a synthetic
consensus splice donor sequence (PGKpuroSD); and 2) a
mutagenic component that incorporates a splice acceptor
5 sequence fused to a selectable, colorimetric marker gene and
followed by a polyadenylation sequence (for example, SAβgeopA
or SAIRESβgeopA). Also like VICTR 3, stop codons have been
engineered into all three reading frames in the region
between the 3' end of the selectable marker and the splice
10 donor site. A diagrammatic description of structure and
functions of VICTRs 3 and 20 is provided in Figure 7.

When VICTRs 3 and 20 were used in the commercial scale
application of the presently disclosed invention, over 3,000
mutagenized ES cell clones were rapidly engineered and
15 obtained. Sequence analysis obtained from these clones has
identified a wide variety of both previously identified and
novel sequences. A representative sampling of previously
known genes that were identified using the presently
described methods is provided in Figure 8. The power of the
20 presently described invention as a genomics resource becomes
apparent when one considers that the genes listed in Figure 8
were obtained and identified in less than a year whereas the
references associated with the identification of the known
genes span a period of roughly two decades. More
25 importantly, the majority of the sequences thus far
identified are novel, and, because of the functional aspects
of the presently described ES cell system, the cellular and
developmental functions of these novel sequences can be
rapidly established.
30

7.0. <u>Reference to Microorganism Deposits</u>

The following plasmids have been deposited at the
American Type Culture Collection (ATCC), Rockville, MD, USA,
under the terms of the Budapest Treaty on the International
35 Recognition of the Deposit of Microorganisms for the Purposes
of Patent Procedure and Regulations thereunder (Budapest
Treaty) and are thus maintained and made available according

to the terms of the Budapest Treaty. Availability of such
plasmids is not to be construed as a license to practice the
invention in contravention of the rights granted under the
authority of any government in accordance with its patent
5 laws.

The deposited cultures have been assigned the indicated
ATCC deposit numbers:

Plasmid	ATCC No.
plex	97748
pExonII	97749
ppuro7	97750
ppuro5	97751
ppuro11	97752
ppuro10	97753

All publications and patents mentioned in the above
specification are herein incorporated by reference. Various
15 modifications and variations of the described method and
system of the invention will be apparent to those skilled in
the art without departing from the scope and spirit of the
invention. Although the invention has been described in
connection with specific preferred embodiments, it should be
20 understood that the invention as claimed should not be unduly
limited to such specific embodiments. Indeed, various
modifications of the above-described modes for carrying out
the invention which are obvious to those skilled in the field
of molecular biology or related fields are intended to be
25 within the scope of the following claims.

CLAIMS

What is claimed is:

1.   A library of cultured eucaryotic cells made by a
process comprising the steps of:

5   a)   treating a first group of cells to stably integrate
a first vector that mediates the splicing of a foreign exon
internal to a cellular transcript;

        b)   treating a second group of cells to stably integrate
a second vector that mediates the splicing of a foreign exon
10 5' to an exon of a cellular transcript; and

        c)   selecting for transduced cells that express the
products encoded by the foreign exons.

2.   A library according to claim 1 wherein said treating
15 is transfection.

3.   A library according to claim 1 wherein said treating
is by infection.

20   4.   A library according to claim 1 wherein said treating
is by retrotransposition.

5.   A library according to any one of claims 1 through 4
wherein said cells are animal cells.

25

6.   A library according to claim 5 wherein said animal
is mammalian.

7.   A library according to claim 6 wherein said cells
30 are rodent cells.

8.   The use of a mutated cell from a library according
to claim 6 to generate a non-human transgenic animal.

35   9.   A vector for replacing the 3' end of an animal cell
transcript with a foreign exon, comprising:
        a)   a selectable marker;

    b)   a splice acceptor site operatively positioned 5' to
the initiation codon of said selectable marker;

    c)   a polyadenylation site operatively positioned 3' to
said selectable marker;

    d)   said vector not comprising a promoter element
operatively positioned 5' of the coding region of
said selectable marker; and

    e)   said vector not comprising a splice donor sequence
operatively positioned between the 3' end of the
coding region of said selectable marker and said
polyadenylation site.

10. A vector for inserting foreign mutagenic
polynucleotide sequence internal to animal cell transcripts,
comprising:

    a)   a foreign exon;

    b)   a splice acceptor sequence operatively positioned
5' to the foreign exon;

    c)   a splice donor site operatively positioned 3' to
said foreign exon;

    d)   a sequence comprising a nested set of stop codons
in each of the three reading frames located between
the 3' end of said foreign exon and said splice
donor site;

    e)   said vector not comprising a polyadenylation site
operatively positioned 3' to said foreign exon; and

    f)   said vector not comprising a promoter element
operatively positioned 5' to the coding region of
said foreign exon.

11. A vector for attaching a foreign exon upstream from
the 3' end of an animal cell transcript, comprising:

    a)   a selectable marker;

    b)   a promoter element operatively positioned 5' to
said selectable marker;

    c)   a splice donor site operatively positioned 3' to
said selectable marker; and

      d)   said vector not comprising a transcription
           terminator or polyadenylation site operatively
           positioned relative to the coding region of said
           selectable marker; and

5   e)   said vector not comprising a splice acceptor site
           operatively positioned between said promoter
           element and the initiation codon of said selectable
           marker.

10   12.   A vector according to claim 11 wherein said vector
additionally comprises a foreign mutagenic polynucleotide
sequence located upstream from said promoter.

      13.   A vector according to claim 12 wherein said vector
15 additionally comprises a splice acceptor operatively
positioned upstream from said foreign mutagenic
polynucleotide sequence.

      14.   A vector according to claim 13 wherein said foreign
20 mutagenic polynucleotide sequence comprises a polyadenylation
site.

      15.   A vector according to claim 14, wherein said
foreign mutagenic polynucleotide sequence additionally
25 comprises stop codons in all three reading frames.

      16.   A vector according to claim 12 in which a first
recombinase recognition sequence is present upstream from
said promoter and a second recombinase recognition sequence
30 is present downstream from said promoter.

      17.   A vector according to any one of claims 9, 10, or
11 wherein said vector is a viral vector.

35   18.   A vector according to claim 17 wherein said viral
vector is a retroviral vector.

19. The use of a vector according to claim 9 to produce a library of mutated animal cells.

20. The use of a vector according to claim 10 to produce mutated animal cells.

21. The use of a vector according to claim 11 to produce mutated animal cells.

22. The use of a vector according to claim 11 to effect homologous recombination in an animal cell.

23. A stably transduced animal cell that incorporates a vector according to claim 16.

24. A method of deleting a region of vector DNA from a cell according to claim 23, comprising:
   a)   providing a recombinase activity to the cell; and
   b)   selecting for cells that lack the desired region of vector DNA.

25. A method of adding a region of DNA to a cell according to claim 23, comprising:
   a)   introducing the DNA to be added into the cell;
   a)   providing a recombinase activity to the cell; and
   b)   selecting for cells that incorporate the added DNA.

26. A method of effecting the inducible expression of a desired gene, comprising:
   a)   providing a cell according to claim 23 with a recombinase gene that is expressed by an inducible promoter; and
   b)   inducing said inducible promoter.

27. A method of gene discovery comprising:
   a)   adding a foreign polynucleotide to a population of target cells such that the foreign

polynucleotide is inserted throughout the genomes of the
target cells; and

       b)   activating control elements encoded by the
foreign polynucleotides that activate or repress the
5 expression of target cell genes that flank the integrated
foreign polynucleotides, and identifying the regions of the
target cell genome into which the foreign polynucleotides
have integrated.

10   28. A library of cultured animal cells that stably
integrate vectors according to claims 10 or 11.

Identify Positive Pool

To screen all mouse genes (~100,000) with 5-fold redundancy would require about 50 plates of 96-wells (at 100 clones/well).

① Pool columns

(100 clones/well)(12 wells) = 1200 clones per rxn.
(50 plates)(8 columns/plate) = 400 initial rxns.

Plate C, column 3 was positive.

② Pool positive rows only
8 rxns per positive plate

Row 8 was positive.
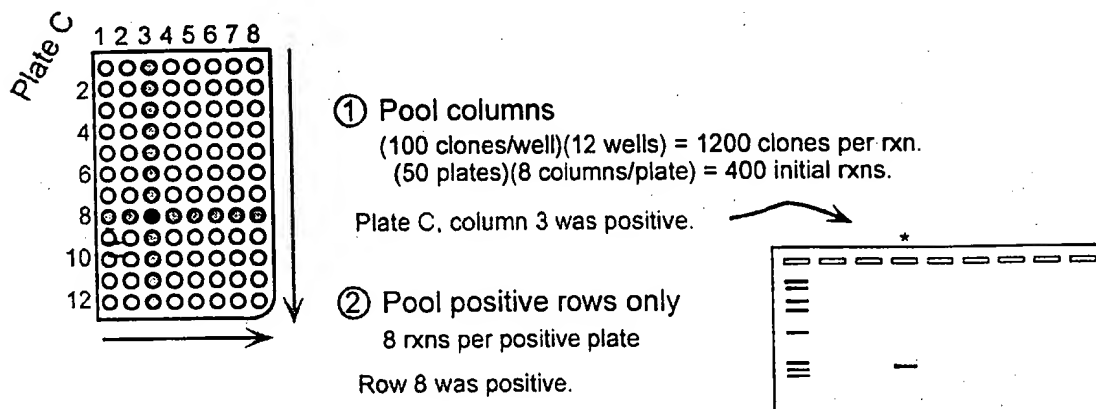

Identify Positive Clone

The pool on plate C, column 3, row 8 is thawed and plated as single clones:

① Pick 96 colonies into
two 96-well plates

② Pool columns (16) and rows (24) for
40 rxns to identify positive clone.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US97/17791

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :C12Q 1/68; C12N 5/02, 5/06, 15/00, 15/64; C07H 21/04
US CL :435/6, 320.1, 325, 357; 536/23.1, 24.2; 800/2

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 435/6, 320.1, 325, 357; 536/23.1, 24.2; 800/2

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS and DIALOG

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US97/17791

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
   because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
   because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
   because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Extra Sheet.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
   1-8, 10, 20 and 28

Remark on Protest   ☐ The additional search fees were accompanied by the applicant's protest.

☐ No protest accompanied the payment of additional search fees.

Form PCT/ISA/210 (continuation of first sheet(1))(July 1992)*

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING
This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single
inventive concept under PCT Rule 13.1.

Group I, claim(s) 1-7, 8, 10, 20 and 28, drawn to a library of cultured eucaryotic cells made by a process comprising
treating a group of cells with a vector that mediates the splicing of a foreign exon internal to a cellular transcript, the
use of the cell from the library to generate a non-human transgenic animal, and the method of making the cell
comprising the vector and the use of the vector to make the library of cultured eukaryotic cells.

Group II, claim(s) 9, 11-18, drawn to a vector construct for replacing the 3' end of an animal cell transcript with a
foreign exon.

Group III, claim(s) 19, 21 and 22, drawn to the use of a vector according to claim 9.
Group IV, claim 23, drawn to a stably transduced animal cell that incorporates the vector of claim 16.
Group V, claims 24-27, drawn to a method of altering a region of DNA by adding or deleting DNA.

The inventions listed as Groups I-V do not relate to a single inventive concept under PCT Rule 13.1 because, under
PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: the first
group contains the product, a library of cultured eukaryotic cell, a method of using the cells to produce a non-human
transgenic animal and a method of making the cells. The additional groups are directed to different vectors having
different compositions than the vector used in the first group, cell lines containing those vector constructs and methods
of altering the cellular genome. The first group contains a vector having a different composition than the other vectors
and therefore the special technical feature present in the first group does not occur in the other groups.
